Food Consumption Patterns and Implications for Poverty Reduction in Pakistan

By

Sohail Jehangir Malik, Hina Nazli, Edward Whitney

Introduction

Pakistan has made significant progress in increasing the per capita availability of all major food items, such as, cereals, meat, milk, sugar, and eggs over time. As a result, the average per capita calorie intake increased from 2078 in 1949-50 to 2450 in 2012-13. Similar trends have been reported for protein and fats (Government of Pakistan, 2014). However, the distribution of these calories is worrisome; disaggregated data shows that nearly half of the population is currently unable to meet its minimum (subsistence) caloric requirements for healthy and productive living (Malik *et al.* 2014). The persistent rise in the price of essential food items since 2008 and the decline in real wages have adversely affected the access to food. These trends have serious implications for food security and poverty in the country. National survey based household level data show that on average households spend nearly half of their total expenditure on food; leaving very little for the other expenditures necessary for safeguarding human welfare (HIES 2010-11). In such a situation a rise in food prices has adverse effects on the welfare of a large proportion of population. Therefore, a fuller understanding of food consumption patterns is essential for determining how changes in prices and real wages affect the well-being of people.

The world food crisis of 2008 highlighted the importance of understanding these behaviours. Rising food prices hurt many developing countries including Pakistan. The world food price index increased by 39.5 percentage points in just two years 2006-2008. And food prices have continued to rise. Since 2006, an increase by 42 percent has been observed in the world food price index. The prices of meats, dairy products, cereals, oils and sugars increased by 31, 59, 60, 47 and 3.6 percent, respectively, during this period (FAO, IFAD and WFP, 2013). Several studies confirm that the food price shock and the resulting global economic recession increased the incidence of food insecurity, hunger, and poverty in many developing countries (see for example Ivanic and Martin, 2008; Harttgen and Klasen, 2012). The studies that examined the impact of increasing food prices on income and poverty in the developing countries of Africa and Asia demonstrated the worsening effects of rising food prices on poverty through declining real income (Ivanic and Martin, 2008; De Hoyos and Medvedev, 2009; World Bank, 2010).. Better understanding of the consumer response to rising and falling prices can help the policymakers to design more pro-poor food policy. Several cross country studies enable a better understanding of the overall response patterns within which individual country behaviours would lie. For example, Regmi and Seale (2010) estimated cross-price elasticities across 114 countries for 9 major consumption categories: food, beverage, and tobacco; clothing and footwear; education; gross rent, fuel, and power; house furnishings and operations; medical care; recreation; transport and communications; and “other” items using the price data of 1996. The results were very interesting and confirmed expectations; an increase in the price of a non-food

good leads to increased food demand in the poorest countries and declining food demand in wealthier countries. However, when price of food increases, demand for non-food items decreases confirming that food is a substitute for non-food items. And then within the food category the impact of price changes on the demand of different food items, ranges from a mean price elasticity from 0.27 to 0.81 (absolute values) in a review of 160 studies in the price elasticity of demand for major food categories conducted by Andreyeva et al (2010). They show that the demand for eggs, sugars, and fats and oils is less elastic as compared to the demand for soft drinks, juices, fruits, meats and cereals.

In Pakistan, Haq et al (2008) and Friedman, Hong and Xiaohui (2011) have measured the extent of welfare losses due to rising food prices in Pakistan by estimating compensating variation. Prices of most of the food items in Pakistan have increased by more than a 100 percent since 2006-07¹. Haq et al (2008) found that after the food price crisis of 2008, an additional Rs 44.3 per adult equivalent per month in urban areas and Rs 40.3 per adult equivalent per month in rural areas are required to maintain the utility at the level 2004-05 level. The recent estimates of compensating variation by Friedman, Hong and Xiaohui (2011) suggests that average households would need an additional 38 percent of their pre-crisis expenditures to maintain their pre-crisis consumption levels. This study found that average household caloric availability fell by almost 8 percent between 2006 and the first half of 2008; and, that urban households were relatively worse off than rural households during the crisis. This study also found that the welfare losses from the 2008 food price crisis had widened the inequality between poor and non-poor and across the provinces in Pakistan.

Over the last four decades several Pakistani economists have examined the effect of price change on consumption patterns through the estimation of price and income elasticities in Pakistan.(Siddiqui, 1982; Burney and Khan, 1991; Malik and Sarwar, 1993; Burki, 1997; Farooq et al., 1999; Shamim and Ahmad, 2007; Haq et al., 2008; 2011). Broadly, these studies found significant differences in the price and income responsiveness of different food items across different population groups (poor vs non-poor) and across geographic regions (provinces and rural-urban areas). Although most studies explicitly controlled for various socioeconomic differences; most of these studies did not control for poverty status and seasonality in estimating the food demand patterns. In addition, the analysis in these studies is mostly based on the data collected before the food price hike (i.e., before 2008). To understand the recent and true extent of the impact of price change on consumer behavior, it is important to control for differences across various socioeconomic aspects including regional location, poverty status, and seasonality when estimating income and price elasticities from a demand system. We estimate such a system using the data from the most recent nationally representative publically available Household

¹ Most of this price increase occurred between 2006-07 to 2008-09. During this period the price of wheat flour increased by 162 percent, price of rice by 207 percent, fresh milk by 101 percent, vegetable ghee by 147 percent, and onion by 140 percent (Government of Pakistan, 2014).

Integrated Economic Survey (HIES) 2010-11, we examine the responsiveness of household consumption to changes in prices or income and the implications of this for poverty reduction. We start with an investigation of food consumption patterns, and then move on to an estimation of the income and price elasticities of demand. With the help of the estimated demand elasticities, we then draw policy implications for poverty reduction.

We categorize food items into ten groups: wheat and wheat flour; rice including all kinds of rice consumed; other cereals; pulses; fruits and vegetables; milk and milk products including desi ghee and butter; meat (beef, mutton, fish and poultry); edible oil; sugar and other sweetener; and other food items (tea, condiments and spices, etc.). Per capita demand elasticities are estimated by controlling for differences in various socioeconomic aspects including poverty status of a household, regional and provincial differences, and seasonality effects. To estimate the income and price elasticities of ten food items, we use the Linear Approximate Almost Ideal Demand System (LA-AIDS) proposed by Deaton and Muellbauer (1980a: 1980b).

This paper is divided into five sections. Methodology and data are described in Section 2. A descriptive analysis of food consumption patterns is presented in Section 3. Section 4 presents a discussion of the results of LA-AIDS model and estimated elasticities. Implications of food consumption patterns for poverty reduction are presented in Section 5. Conclusions and policy recommendations are given in the final section.

2. Methodology and Data

2.1 Methodology

To estimate the income and price elasticities of ten food items, we use the Linear Approximate Almost Ideal Demand System (LA-AIDS) proposed by Deaton and Muellbauer (1980a: 1980b). This demand system derives budget share equation from the specification of Price Independent Generalized Logarithmic (PIGLOG) cost function introduced by Muellbauer (1976). The model has budget shares as dependent variables and logarithm of prices and real expenditure/income as regressors. The LA-AIDS model satisfies the desirable properties of a demand theory. The LA-AIDS demand equation in budget share form is:

$$w_i = \alpha_i + \sum_{j=1}^n \gamma_{ij} + \ln(p_j) + \beta_i \ln\left(\frac{x}{P}\right) + e_i \quad (1)$$

In equation (1), n is the number of goods, w_i is the budget share of good i , p_j is the price of good j , x is expenditure, P is a price index approximated by the Stone price index ($\ln(P) = \sum_j w_j \ln(p_j)$) and α_i , γ_{ij} , and β_i are parameters. Separability is imposed at the food level, implying that consumers modify their optimal food consumption bundle when relative prices of individual foods change, given an optimal allocation of expenditure on food. Due to separability, the marginal rate of substitution between any food items is independent of the changes in the non-food items.

To account for the household characteristics, Equation (1) is augmented with household specific socio-economic, demographic, provincial, and regional (briefly socio-economic) characteristics using the following relationship proposed by Pollak and Wales (1981).

$$\alpha_i = \alpha_i^* + \sum_j \delta_{ij} z_j \quad (2)$$

where z_j is a matrix of socio-economic variables and δ_{ij} is the vector of parameters. Substituting Equation (2) in the Equation (1) yields:

$$w_i = \alpha_i^* + \sum_{j=1}^n \gamma_{ij} + \ln(p_j) + \beta_i \ln\left(\frac{x}{p}\right) + \sum_{j=1}^n \delta_{ij} z_j + e_i \quad (3)$$

Equation (3) is estimated for ten food items mentioned above for whole Pakistan. The theoretical restrictions on the demand function are imposed during estimation. These restriction include the following:

Adding-up:

$$\sum_i^n \alpha_i^* = 1, \quad \sum_i^n \gamma_{ij} = 0, \quad \sum_i^n \beta_i = 0 \quad \forall \text{ all } i \quad (4)$$

Homogeneity:

$$\sum_i^n \gamma_{ij} = 0, \quad \forall j \quad (5)$$

Symmetry:

$$\gamma_{ij} = \gamma_{ji} \quad (6)$$

Using equation (3), uncompensated, compensated, and expenditure elasticities can be derived.

The uncompensated price elasticity for good i with respect to good j is $e_{ij} = \frac{\gamma_{ij} - \beta_i}{w_i} - \delta_{ij}$.

Compensated price elasticity for good i with respect to good j is $e_{ij} = \frac{\gamma_{ij}}{w_i} + w_j - \delta_{ij}$, Where δ_{ij}

is the Kronecker delta and it equals one for own price and zero for cross-price elasticities. The

expenditure elasticity (E_i) is $E_i = 1 + \frac{\beta_i}{w_i}$.

The seemingly unrelated regression estimation method of Zellner (1963) is employed to estimate the system of equations. The statistical significance of the estimated elasticities are derived using the delta method. Imposing the property of additivity of the expenditure function makes the variance and covariance matrix singular and one of the equations needs to be omitted to estimate the LA-AIDS. The expenditure equation for “other food” is omitted and the coefficients for the omitted equation are derived using the theoretical conditions imposed on the estimation process. However, the coefficients estimated using LA-AIDS are invariant to the omitted equation.

2.2 Data

The data used in this study is derived from the nationally representative Household Integrated Economic Survey (HIES) 2010-11 (the most recent data available). HIES 2010-11 covers 16,341 households selected from the urban and rural areas of all four provinces of Pakistan. A two-stage stratified random sample design was adopted to select the household's. In the first stage, 1,180 primary sampling units (enumeration blocks) were selected in the urban and rural areas of all four Pakistan provinces. In the second stage, the sample of 16,341 households was randomly selected from these primary sampling units. Using a random systematic sampling scheme with a random start, either 16 or 12 households were selected from each primary sampling unit (GOP, 2011). The HIES collects detailed information on the quantity and value of consumption of various food items. This information enables us to examine the budget share of different food items to estimate the LA-AIDS system. In addition, HIES collects data on various household and individual characteristics that allows the estimation of LA-AIDS demand system by controlling for various factors other than prices and income.

3. Consumption Patterns of Food

In this section we examine the underlying food budget shares, calories consumption and the cost of calories across poor and non-poor households by urban or rural households. We classify households who fall in the lowest two per capita expenditure quintiles².

3.1 Food budget shares

Food accounts for 54 percent of total expenditure; 46 percent in urban areas and 58 percent in rural areas. Of total expenditure, non-poor spend about 51 percent and poor 57 percent on food. On average Rs.1695 per adult equivalent per month are spent on food; Rs.1137 by the poor and Rs.2070 by the non-poor. Cereals and dairy products are important food items in the diet of Pakistani households. These two food groups constitute nearly 46 percent of total food expenditure. Wheat is the most important cereal, accounts 22 percent of the food expenditures for the poor; 20 percent in urban areas and 22.9 percent in rural areas. Whereas, non-poor households spend 14.5 percent of food expenditure on wheat; 11.9 percent in urban areas and 15.9 percent in rural areas. Relative to wheat, rice accounts for only one fourth of wheat's expenditure share. Other cereals make up less than half a percentage of the food expenditures across the board (Table 1).

The share of expenditures on dairy products is higher than the share for cereals. Similar trends are observed for urban and rural areas. Poor spend more on wheat and non-poor on dairy products. Most of the dairy products are consumed in the form of milk and ghee. The other important categories but with much lower shares are fruits and vegetables, oils, and sugar. These

² The average calories consumption for households who fall in these two lowest quintiles is 2260 per capita which is lower than the nationally accepted poverty line consumption of 2350 per ae per day.

food groups account for 13 percent, 10.8 percent, and 10.5 percent, respectively of food expenditures. Pulses make up about 3 percent of the total food expenditures.

Table 1: Budget Shares by Food Groups; by Urban and Rural and poverty status

Food group	Urban			Rural			Pakistan		
	Overall	Non-poor	Poor	Overall	Non-poor	Poor	Overall	Non-poor	Poor
Share of food expenditure in total expenditure (%)	46.5	42.5	52.4	57.6	56.1	60	53.8	51.4	57.4
Share in food expenditure (%)

3.2 Calorie consumption

The HIES provides information on the consumed quantities of various food items. The consumption aggregate includes not only actual purchases but also self-produced and consumed items, consumption of items that were received as gifts, plus items provided in place of monetary compensation. Using the Food Composition Tables for Pakistan (2001), we converted these quantities into calories. The average calorie consumption is reported in Table 2. This table shows that wheat provides bulk of calories. Nearly 52 percent of the calories come from wheat for poor households. This proportion is higher in rural areas than that in urban areas. The second largest source of calories for the poor is cooking oil/fats followed by dairy products and sugars. The expenditure and calorie intake patterns signify an unhealthy diet patterns of the people of Pakistan.

Despite calorie-dense diet, the overall per adult equivalent per day calorie intake (2260) is less than the officially recommended minimum per day intake of 2350 calories. The average calorie intake for the poor (1848) is significantly lower than the recommended intake of calories. The calorie intake of urban poor is lower than the rural poor.

In 2011, the Nutrition Section of the Planning Division developed the national level food basket based on minimum essential common food items. The food basket was targeted to provide 2150 calories and about 65 gm of protein per day per person. This basket consists of wheat (10

kg/month), rice (2.3 kg/month), pulses (1 kg/month), milk (4.5 liter/month), meat (1.3 kg/month), oils and fats (1.25 kg/month), sweetener (1.5 kg/month), and fruits and vegetables (10.5 kg/month). Converting per day quantities into values using the prices of 2010-11 indicates that an adult needs Rs 56 per day (Rs 1670 per month) to buy food that can provide 2150 calories. The data reported in Table 2 shows that the poor households, irrespective of the place of residence, are not able to obtain 2150 calories per day.

Table 2: Calorie shares of Food Items (%) by Urban, Rural and Poverty Status (2010-11)

Food groups	Urban			Rural			Pakistan		
	Overall	Non-Poor	Poor	Overall	Non-Poor	Poor	Overall	Non-Poor	Poor
Total calories per adult equivalent per day	2,086	2,289	1,782	2,351	2,664	1,882	2,260	2,535	1,848
% share in total calories									
Wheat	42.6	38.2	49.2	48.6	45.4	53.3	46.5	43.0	51.9
Rice	6.0	6.0	6.1	5.3	5.4	5.2	5.6	5.6	5.5
Other Cereals	0.5	0.5	0.3	0.7	0.8	0.6	0.6	0.7	0.5
Pulses	2.6	2.7	2.5	2.2	2.3	2.0	2.3	2.4	2.2

3.3 Cost of calories

The evidence indicates that the Pakistani diet is not calorie efficient in terms of expenditures. The cost per calorie varies significantly across rural urban areas and poverty status. Using the average food expenditure per adult equivalent per day and calories per adult equivalent per day, we computed the average cost of 100 calorie. In view of the importance of wheat, we also computed the cost of 100 calories derived from wheat. Results are presented in Table 3. This table shows that non-poor spend more to obtain 100 calories both in urban as well as rural areas. Overall a household spends Rs 2.52 to obtain 100 calories. However, looking at the cost of calories from wheat (last column), one can note that poor are paying a higher amount to get 100 calories from wheat than the non-poor. Calories, especially from wheat that is the major source of calories, can become more expensive if prices of wheat continue to rise.

Table 3: Calories consumed and the cost of calories (kcal/rupee)

Region or Population Group	Population % of total	Total Calories (daily per A.E)	Food Expenditure (daily per A.E.) (Rs)	100 Calories cost Overall Food (Rs)	Expenditure on Wheat (per adult equivalent) (Rs)	Calories from wheat (daily per A.E.)	100 Calories cost Wheat (Rs)
Rural Poor	31.2	1,882	36.77	1.95	8.15	1,006.9	0.81
Rural Non-Poor	35.6	2,664	67.00	2.52	7.73	1,207.6	0.64

4. Estimated Demand Elasticities

In this section we present estimates from the Linear Approximate Almost Ideal Demand System LA-AIDS model for the 2010-11 data discussed above. Per capita demand elasticities are estimated by controlling for various socioeconomic variables including poverty status of a household, regional and provincial differences, and seasonality effects. Food items are categorized into ten groups: wheat and wheat flour; rice including all kinds of rice consumed; other cereals; pulses; fruits and vegetables; milk and milk products including desi ghee and butter; meat (beef, mutton, fish and poultry); edible oil; sugar and other sweetener; and other food items (tea, condiments and spices, etc.).

The HIES does not collect information on prices of food items for each household. However, it collects data on the quantity consumed and total expenditure on food items in detail. This enables us to calculate the unit value of consumed food items for each household. These unit values are used as proxy of prices³ in our estimation. In addition to prices and household per capita food expenditure, several socioeconomic variables are included in the model: three binary variables indicating three levels of education (primary, middle, and high) of the household head; binary variables representing employment of the household head (self-employed, farmer, employee); three dummies representing the quarter when data were collected; dummies representing the provinces of Punjab, Sind and Khyber Pakhtunkhwa (KPK), urban/rural areas and poverty status. The HIES survey is conducted over four quarters of the year. This enables us to test explicitly for differences in consumption across seasons.

³ Since all items are not consumed by all households the problem of missing prices arises. In order to keep these missing observations in the analysis, we followed Cox and Wohlgemant (1986) and replaced the missing prices with the average price of an item prevailing in the primary sampling unit (PSU).

The model results confirm differences in consumption patterns observed in the tabular analysis presented in the previous section. Statistical tests for the similarity of provincial, regional and socioeconomic effects included in the model estimation are strongly rejected thus confirming that food demand pattern differ significantly across provinces, urban/rural areas, poverty status, seasons, and socioeconomic groups (Table 4).

Table 4: Tests of hypotheses for the similarity consumption behavior

Null Hypothesis	Wald test		
	(chi-square)	Critical value	Decision
H ₀ : No provincial effects	8037 (27)	40.11	Reject H ₀
H ₀ : No provincial and urban/rural effects	9116 (36)	55.75	Reject H ₀
H ₀ : No seasonal effects	807 (27)	40.11	Reject H ₀
H ₀ : No difference between poor and non-poor	2124 (9)	16.92	Reject H ₀
H ₀ : No effect of socio-economic variables	1663 (54)	79.08	Reject H ₀

Source: Authors estimation based on HIES 2010-11

4.1 Estimated LA-AIDS model

The descriptive statistics show this variation in the prices of food items across region (rural/urban) and poverty status. These are presented in Annexure Table 1. Prices are higher in urban areas than that in rural areas and non-poor households pay more as compared to poor households. The socio-economic variables indicate that household residing in urban areas are better than the rural households and non-poor households are better than the poor households in terms of education. A majority of households is engaged in wage employment and this proportion is not very different across rural/urban area or poverty status. A percentage of the rural population is poor (48%) as compared to urban areas (25%).

Most of the estimated coefficients from the model are significant at least at the 95 percent level of significance. The estimated equations for the ten food items are presented in Annexure Table 2. Significant differences in consumption patterns are observed between urban and rural areas, among provinces, and across poverty status. For example, urban households spend less on wheat, rice, other cereals, pulses, edible oil, and sugar and more on fruits and vegetables, dairy and meat than the rural households. The expenditure share of wheat is lower and rice is higher in all provinces as compared to Baluchistan (the reference province). The expenditure on pulses, fruits and vegetables, meat and sugar is significantly higher and the consumption of dairy is significantly lower in Baluchistan as compared to other provinces. The results indicate that household where head is educated up to the primary level consume more rice, other cereals and edible oils. The consumption of dairy products and meat significantly increases and that of edible oil and sugar decreases as education improves. Results show a significant decline in wheat consumption as education improves. Farm households spend significantly more on rice and other cereals and dairy as compared to non-farm households. However, no significant difference in the consumption of wheat between farm and non-farm households is observed. This table shows significant differences for poor and non-poor households. For example, comparing with non-

poor households, poor households spend more on cereals, dairy, and sugar and less on meat, fruits and vegetables.

These results confirm a priori expectations. There are significant seasonality effects. For example, wheat consumption is higher in quarter 4 (April-June), the period after wheat harvest. However, the seasonality effect in wheat consumption appear insignificant. Rice consumption is higher in quarter 3 (January-March), the period after rice harvest. Meat consumption is found to be statistically significantly higher in quarter 2 (October-December). Eid-ul-Adha, was celebrated in the second quarter in November in 2011. The consumption of fruits and vegetables is higher in the first quarter (July-September). These are the months when a variety of fruits and vegetables become available in the market.

4.2 Expenditure elasticities

Based on these estimates from the LA-AIDS model, we computed expenditure elasticities by rural and urban areas, and poverty status (see Table 5). Overall the expenditure elasticities are positive and significant suggesting that all goods are normal. The elasticities are greater than one for dairy and close to unity for rice, and sugar suggesting that these food items are most responsive to expenditure changes or luxuries. Similar patterns are observed for rural and urban areas. The elasticities of wheat and pulses appear slightly more elastic for rural areas as compared with urban areas. This indicates that a small change in expenditure affects the demand of these two items more in the rural areas. Comparing poor and non-poor households, Table 5 shows that poor households are more responsive to any changes in expenditures in both urban as well as rural areas. However, comparing the poor households across urban and rural areas, the results in Table 5 show that the urban poor are more responsive to expenditure changes than the rural poor for all food items except for pulses and meats. Any change in the expenditure of these two food items changes their demand more for urban poor. For non-poor households of urban areas, the expenditure elasticity of rice, meat, dairy products, fruits and vegetables, and sugar falls in the range of 0.938 to 1.449. This indicates that the demand of these items changes more with a change in expenditure. Similar pattern, with a slightly lower value of the elasticities, is observed for rural non-poor. These results clearly show that a rise in income results in increasing the demand for expensive food items for poor as well as non-poor households both in urban and rural areas.

Table 5: Expenditure Elasticities of Demand (2010-11)

Food groups	Rural areas			Urban areas			Pakistan		
	Poor	Non-poor	Overall	Poor	Non-poor	Overall	Poor	Non-poor	Overall
Wheat	0.835	0.754	0.792	0.915	0.668	0.736	0.849	0.715	0.770
Rice	0.882	0.758	0.832	1.237	0.938	1.026	0.945	0.829	0.913
Other Cereals	0.129	1.227	0.791	0.252	1.134	1.024	0.072	1.259	0.890

4.3 Own and cross price elasticities

Own and cross price elasticities represent consumers' response to price change. To examine the welfare effect of price change, we computed uncompensated as well as compensated price elasticities. The uncompensated elasticity of demand represents changes in the quantity demanded as a result of changes in prices, capturing both substitution and income effect, whereas, compensated elasticity of demand describes only the substitution effect as a result of price change, keeping the level of utility constant. The demand for most of the commodities (except 'other cereals' in rural areas) is price inelastic (Table 6). These elasticities are statistically significant and have the expected signs. Compensated price elasticities are less than the uncompensated elasticities indicates that all the goods are normal. These elasticities show the responsiveness to prices and determine the consumption patterns of poor and non-poor households in the rural and urban areas of Pakistan.

A perusal of Table 6 shows some interesting findings. For example, the demand for most of the commodities (except 'other cereals') is price inelastic, ranging from -0.21 (cooking oil) to -0.77 (dairy). Cooking oil appeared least responsive to price change, both in rural as well urban areas irrespective of the poverty status. However, the absolute value of elasticity is the lowest for the urban poor. Poor and non-poor households respond in similar manner to the price change of dairy products in urban areas. The own price elasticity of 'other cereals' is greater than one indicates high responsiveness to price changes. However, rural-urban disaggregation shows 'other cereals' are inelastic for urban households and highly elastic for rural households. The price elasticity of rice in urban areas, especially for poor appeared relatively high. Wheat and

other cereals are less price responsive for urban non-poor households. Although poor and non-poor households respond differently for the change in prices of fruits and vegetables, and sugar within rural or urban areas, the response behaviour of rural poor and urban poor, and rural non-poor and urban non-poor is similar. A considerable difference between uncompensated and compensated elasticities of wheat (-0.317 and -0.178) and dairy (-0.769 and -0.396) for all households irrespective of the place of residence and poverty status is observed. This indicates that maintaining the same utility level after a price change reduces the price responsiveness of these two food items.

Cross price elasticities indicate the effect of a price change in one commodity on the demand for another commodity. The estimated uncompensated and compensated cross price elasticities for rural areas, urban areas and overall Pakistan are reported in Tables 7, 8, and 9, respectively. Uncompensated elasticities indicate that most of the food items are complements of each other (negative cross price elasticities). However, if household expenditures are adjusted (compensated) to keep them at the old utility level, most of the food items become substitutes. This means that when price increases are offset by equivalent income increases to maintain the original utility level, households make substitution. The number of substitutes is higher in rural areas as compared to urban areas.

The low and insignificant value of the cross price elasticity of wheat and rice suggests that the consumption of wheat and rice are largely independent of price changes of either commodity which may illustrate the strong individual household preference for wheat and rice in Pakistan. A positive and significant cross price elasticity of wheat with other cereals indicates that households substitute other cereals in case of an increase in wheat price, or vice-versa. This result is consistent with the findings of Farooq et al. (1999), Haq et al. (2011). The importance of dairy and its products can be observed through the complementarity between dairy products and all other food items. An increase in the price of other food items reduces the demand for dairy and its products. However, an adjustment in expenditure to offset the price increase of other food items allows substitution for dairy products. This situation holds in both urban and rural areas.

Our results confirm the importance of wheat and dairy products for the households in Pakistan irrespective of the place of residence. Other cereals including rice appear to be the weak substitutes of wheat.

5. Food Consumption Patterns and Implications for Poverty Reduction

Results presented in tables 5-9 reinforce the importance of wheat for all households irrespective of their place of residence and poverty status. The average availability of wheat has fluctuated around 10 kg per capita per month since 2001-02 while the per capita consumption has remained lower not only than the per capita availability but also than the recommended quantity of 10 kg per capita per month (Government of Pakistan, 2011b). The overall gap between total availability and consumption has been increasing over time⁴ (see Table 10).

The price of wheat has an important impact on the welfare of the people. Available data show that an increase in the price of wheat resulted in significantly reducing the purchasing power of skilled and unskilled labour. The nominal daily wages of skilled as well as unskilled labour has increased by more than double during 2001-02 to 2010-11. However, due to increase in the price of wheat, purchasing power (for wheat) of skilled and unskilled labour has declined by 34 and 32 percent respectively. In 2001-02, skilled labour in Lahore could buy 30.8 kg of wheat with his/her daily wage. This quantity declined to 20.4 kg in 2010-11 (see Table 10). An increasing trend in wheat prices and resultant decline in the purchasing power and reduction in wheat consumption has serious implications for food security, nutritional status, and poverty.

Table 10: Per capita availability, consumption, and price of wheat

	Wheat availability and consumption (kg/month)			Price (Rs/kg)	Daily wage in Lahore (Rs/day)		Wheat flour quantity can be bought with daily wage in Lahore (kg)	
	Avail-ability	Consum-ption	Gap		Skilled labour	Unskilled labour	Skilled labour	Unskilled labour

Source: For wheat availability: Government of Pakistan (2011a), Agriculture Statistics of Pakistan

For consumption: HIES (various issues)

For wheat prices and daily wages: Government of Pakistan (2014), Economic Survey 2013-14

As discussed earlier that wheat is the most important food item in the diet of Pakistani households, provides bulk of calories (almost 48 percent). Its demand is very inelastic and preferences are very strong. An increase in the price of wheat may not result in substitution with other food items. However, substitution with non-food items is possible. A substitution with health and education may worsen the already low human development indicators and may have adverse effect on already high levels of poverty in the country. This has serious implications not

⁴ A smaller value of gap in 2010-11 is driven by decline in the per capita availability of wheat.

only for the money metric measures of poverty but also for other human development indicators, especially for the nutritional status.

As discussed in Section 3, Pakistani diet is dense in calories and macronutrients and deficient in micronutrient. Available national data show that the outcomes of micronutrient deficiency are noticeable amongst women and children. The results of the National Nutrition Survey (NNS) (2010-11) indicate that nearly half of the women of child-bearing age are suffering from anemia, 43 percent in vitamin A deficiency, 48 percent in zinc deficiency, and 69 percent in vitamin D deficiency. A large number of children under five years of age suffer from the vitamin A deficiency (54%), zinc deficiency (39%), and iron deficiency (62%). In addition, the prevalence of protein-energy malnutrition (PEM) is not only high but has also increased over time. In 2011 nearly 44 percent children were estimated to be stunted, 15 percent were wasted, and 32 percent were underweight. These proportions were 32.5 percent stunted, 11.2 percent wasted and 42.3 percent underweight in 2001. About 15 percent of Pakistan's population consists of children under five years of age.

The high incidence of malnutrition amongst children has adverse effects on their intellectual development and consequently, their health and productivity in later life. A reduction in the purchasing power of the wage earners can further aggravate the situation. If the issues of limited dietary diversity, persistently rising prices of food, and increasing incidence of malnutrition are not addressed through appropriate policy measures, the already alarming situation is likely to get worse. Addressing this alarming situation requires urgent development and implementation of appropriate policies and, more importantly, awareness building about the gravity of the situation.

6. Conclusions and Policy Implications

Our analysis highlights several critical aspects of the situation. These are summarized below:

Limited dietary diversity amongst Pakistani households: Nearly 70 percent of food expenditure is spent on energy-dense diet. Cereals and dairy products constitute 46 percent of total food expenditure. Poor spend more on wheat and non-poor on dairy products. The other important categories are cooking oil and sugar. Pulses which are eaten by most of the poor people of Pakistan make up about 3 percent of the total food expenditures.

A large proportion of households consume less than the recommended amount of calories: The overall per day calorie intake (2260) is less than the officially recommended minimum per day intake of 2350 calories. The average calorie intake for the poor (1848) is significantly lower than the recommended intake of calories. The calorie intake of urban poor is lower than the rural poor.

Consumption patterns vary across rural and urban areas and for poor and non-poor households: Differences in the elasticity estimates indicate varying consumption patterns across regions (rural and urban areas) and poverty status (poor and non-poor). Dairy appeared a luxury food item for all households irrespective of their area of residence or poverty status. Urban non-poor are more income responsive for other cereals, fruits and vegetables, and sugar. As compared to poor households, the non-poor are less responsive to price change for all commodities. Dairy products are highly price responsive for poor and non-poor in urban as well as rural areas. Wheat, other cereals, cooking oil appeared least responsive to price change, both in rural as well urban areas irrespective of the poverty status. The responsiveness of rice to income and prices appeared relatively high for the urban poor. The response behaviour of poor and non-poor across rural and urban areas is similar for fruits and vegetables, and sugar.

Households maintain the original utility levels by making substitution: Uncompensated elasticities indicate that most of the food items are complements of each other (negative cross price elasticities). However, if household expenditures are adjusted to keep them at the old utility level, most of the food items become substitutes. A considerable difference between uncompensated and compensated elasticities of wheat (-0.317 and -0.178) and dairy (-0.769 and -0.396) for all households irrespective of the place of residence and poverty indicates that maintaining the same utility level after a price change reduces the price responsiveness of these two food items. Often this substitution means foregoing other critical consumption required to maintain a balanced diet.

Rising prices of wheat adversely effects calorie consumption and poverty status if it is measured in terms of calorie intake: Wheat is the major source of calories. Poor households derive nearly 52 percent of total calories from wheat. Poor spend more to obtain 100 calories as compared to non-poor households, both in urban as well as rural areas. Highly inelastic own price elasticity of wheat and insignificant substitution between wheat and rice indicates the importance of wheat, particularly for urban consumers. An increase in the price of wheat may not reduce its consumption but may result in a decline in the expenditure on other non-food items, such as, education and health. An increase in wheat price may be helpful for the wheat growers who are net sellers. These growers form a small percentage of all wheat consumers. All net buyers of wheat suffer and this includes all the urban and no farm households as well as all the producers who are not net sellers. It is therefore important to evaluate the effect of increasing wheat prices in a broader framework.

A reduction in the purchasing power as a result of increase in the prices of essential food items has adverse effects on food security and prevalence of malnutrition in Pakistan. If the issues of limited dietary diversity, persistently rising prices of food, and issue of food security are not urgently addressed through appropriate policy measures, the situation will get worse. Addressing

this alarming situation requires appropriate policies and, more importantly, awareness building about the gravity of the situation.
