EXTERNAL DEBT AND CAPITAL ACCUMULATION NEXUS: EVIDENCE FROM PAKISTAN

Tahir Mukhtar[•] and Abida Yousaf[••]

Abstract: *The rising public debt burden is a common feature of the developing countries like Pakistan. This study is an attempt to empirically analyze external debt and capital accumulation nexus for Pakistan over the time period 1972 to 2016. The ARDL bound testing technique has been employed to estimate two different models which incorporate different indicators of external debt. Results indicate the existence of negative relationship between external debt to revenue ratio and stock of capital which supports the debt overhang hypothesis for Pakistan which states that large accumulated debt leads to decrease overall capital accumulation in an economy. Similarly, other indicators of external debt, namely, external debt service to revenue ratio, external debt to export ratio and external debt service to export ratio tend to bring a fall in stock of capital in Pakistan. On the basis of its findings the study suggests the need for better and productive use of external debt in public sector development project to foster the capital accumulation process in Pakistan.*
Keywords: External Debt; Capital Accumulation; Human Capital; ARDL.

1. Introduction

The continuous increase in the external debt burdens of the low income countries is an indicator of economic slowdown and the lack of prudent debt management. In this regard, inappropriate structural reforms, lack of sustainable macroeconomic adjustment policies, lack of diversified export bases and political instability are considered as main drivers of the higher external debt burdens. The immediate effect of the increasing debt can be observed through the

decline in both domestic and the net foreign investment which further result in lower capital accumulation and output in an economy. Additionally, higher public debt not only crowds out the physical capital but also adversely affects human capital accumulation (Serieux and Samy, 2001).

Economic theory postulates that rational borrowings encourage economic growth through factor accumulation and productivity growth. This is due to the reason that countries at their early stages of development generally tend to have smaller capital stocks with limited and inadequate investment opportunities. As a result, such countries assure higher rates of return on investment (Hameed et al., 2008). However, in case of developing countries the increasing debt burdens are posing a serious threat to the macroeconomic stability through affecting domestic investment and foreign direct investment. No doubt, supplementing resources by foreign economic assistance is important for initiating and accelerating the pace of economic growth. However, a persistent surge in the external debt burden for a longer period of time can create some serious constraints for the economic growth of a country. There is a close relationship between the nature of the debt and economic activity. We can classify debts as productive debt and unproductive debt. A productive debt is one which is raised for productive purposes and it increases the productive capacity of an economy. On the other hand, unproductive debts are not self-liquidating and these debts also do not enhance the productive capacity of the economy. Thus, the debt financed investment should be productive so that it can earn a return higher than the cost of raising the debt (Adebusola et al., 2007).

Like many other developing countries, Pakistan is also confronted with the shortage of financial resources. To cure this problem Pakistan has been bridging its resource gap through borrowing from external resources. Pakistan has been receiving foreign economic assistance since early 1950s for the development requirements of its economy. The foreign aid has played an

important role in the medium and long term development programs in Pakistan. The foreign economic support (loans, credits and grants) is mostly categorized as project aid and non-project aid. The main objective of the foreign assistance has been to complement the domestic resources required to speed up the pace of economic development process in the country. The debt burden continues to increase during 1980s and 1990s. Debt situation in Pakistan reached a vulnerable level in 1999 due to large and persistence current account and primary fiscal deficits. This twin deficit resulted in the unstable accumulation of huge total debt. During the first half of the 1980s domestic debt increases by 8 percent and followed by even a higher rate of 22 percent in the second half of the 1980s (Adnan, 2008). The domestic and external debt situation got worsen during 1990s. The external debt to GDP ratio increased to 43 percent in 1998-99 from 34 percent in 1990-91 while the domestic debt grew at a rate of 13.7 percent per annum during 1990s (Pakistan, 1999-00).

With severe financial problems Pakistan entered in the 21st Century. Public debt exceeded the revenues by more than 600 percent and it stood at 90 percent of GDP. At the same time, debt repayments accounted for more than half of the current revenues. In 2001, the World Bank declared Pakistan as a severely indebted South Asian country. Due to the weak financial position of the country Paris Club members and quasi-London Club rescheduled the debt payments several times during 1998 to 2001 (Zaidi, 2015).

After 2001, economic and public debt indicators showed some improvement in Pakistan. But unfortunately, this trend could not be persisted for a longer time period. In last few years Pakistan is facing massive fiscal and current account deficits. The expansion of the fiscal and current account deficits resulted in the higher borrowing through both internal and external sources to finance these deficits. The domestic and external debt has increased to Rs.3 trillion and Rs. 3.4 trillion respectively. The public debt as a percentage of GDP increased to 61.6 percent in FY2012-

13 from 55.2 percent in FY2006-07. Similarly, public debt as a percentage of revenue during 2016-17 fell to 442.5 percent from 479.2 percent in 2012-13 (Pakistan, 2016-17).

The present study aims to explore the nature of relationship between external debt and capital accumulation in Pakistan. This exercise will enable us to properly understand the consequences of various indicators of external debt burden for domestic capital accumulation in the country. Moreover, the findings of the study will provide us an opportunity to suggest suitable measures for enhancing the stock of capital by optimal utilization of external borrowing. The significance of the study is apparent from the fact that it is first of its nature in the context of Pakistan which has endeavoured to gauge the relationship between some indicators of external debt burden and capital accumulation in Pakistan. Up to the best of our knowledge this type of research has not ever been conducted in case of Pakistan.

The remainder of the study is structured as follows: in section 2 survey of relevant literature is given; section 3 presents estimation strategy and data; in section 4 main empirical results are discussed; and section 5 concludes the study.

2. Literature Review

Both the empirical and theoretical literature available on the nexus between external debt and capital accumulation confirm the deleterious consequences of external debt for capital accumulation. According to Krugman (1988) when the debt obligations in a country crossed the adequate level of borrowings then it discourages the investment. This also implies that at higher level of debt burdens investors would expect lower profits on their investments because they anticipate that in order to payback these outstanding debts the government will increase taxes. Thus, large debt burdens discourage investment and hence slower down the capital accumulation

process. Similarly, Agenor and Montiel (1996) argue that higher debt burdens affect the growth through lowering the total factor productivity growth.

Only few studies have directly analyzed the impact of foreign debt on capital accumulation. The findings of Gong and Zou (2000) reveal that foreign aid negatively affect capital accumulation in the long run. Whereas, in the short run the relationship is positive because in the short run increase in foreign aid increases the investment and capital accumulation and reduces the external borrowings. Habimana (2005) investigates the nature of the relationship between the higher level of external debt and capital accumulation in Rwanda. The findings of the study reveal a negative effect of external debt on capital accumulation process. It implies that the continuous increase in the debt burden can result in various macroeconomics effects including the reduction in capital stock via decrease in domestic investment and lower output level in an economy. Cohen (1993), Wagner (1996), Deshpande (1997), Elmendorf and Mankiw, (1998), Serieux and Samy (2001), Were (2001), Clements et al.(2003) and Sen et al.(2007) investigate the impact of foreign debt on growth via investment channel which is also called debt overhang hypothesis. All these studies support the existence of the debt overhang hypothesis.

We have come across quite a few studies which have attempted to investigate investment response to external debt in Pakistan. To this end Chishti and Hasan (1992) analyzing the impact of foreign aid (grants and loans) on investment and consumption activities in public sector of Pakistan show that foreign aid in the form of grant shows a modest impact on public investment but foreign aid in the form of loan have robust effect on public investment in Pakistan. Chaudhry et al. (2009) investigate the effects of external debt on saving and investment in Pakistan for the period of 1973-2006. The authors conclude a positive but marginally significant impact of foreign debt on investment levels. The authors are of the opinion that inflows of foreign debt have

favorable impacts on investment expenditures in Pakistan. Jafri and Hira (2012) analyze the impact of external debt service payments on the investment. The findings of the study show that the debt services to the multilateral and private creditors have a significant impact on the gross private capital investment in case of Pakistan. Results also suggest that the impact of the external debt service payments on investment is dependent on the nature of credit institutions. The debt services to multilateral creditors and other private creditors negatively affect the gross private capital investment in Pakistan. However, this situation reverses in case of debt servicing to the bilateral creditors. Ali (2013) focuses on estimating the impact of external debt, foreign direct investment and worker's remittances on domestic investment in Pakistan from 1972 to 2007. The time series analysis concludes a significant investment increasing impact of foreign debt inflows into the Pakistan economy. Although the impact of external debt on domestic investment is positive and significant yet the study suggests that foreign debt should be utilized for indispensable purposes.

It is an undeniable fact that domestic capital accumulation plays a critical role to determine the trajectory of growth and similarly, foreign debt has a vital role to play for complimenting domestic resources in developing countries to speed up the process of capital accumulation and economic growth. Unfortunately, there is dearth of literature having focused on gauging the role of various indicators of external debt burden on the process of capital accumulation in a developing country like Pakistan. The present study is aimed to fill this vacuum in the related literature.

3. Theoretical Framework

3.1 Econometric Model

To gauge the effect of external debt on capital accumulation we estimate two physical capital stock models. These models include debt to revenue ratios and debt to export ratios as

explanatory variables along with some control variables. Debt to revenue ratios are used in order to capture the "crowding out" effects, while the debt to exports ratios serve to explore the "import compression" effects. The model is borrowed from Serieux and Samy (2001), in their study on the nature of the relationship between debt and growth, in a cross section of 53 low and lower-middle income countries covering the period 1970 to 1999, where they estimate an investment equation, a human capital growth equation, and a growth equation. Thus, we specify our econometric models as:

$$KS_t = \alpha_0 + \alpha_1 GDPGR_t + \alpha_2 DR_t + \alpha_3 DSR_t + \alpha_4 INF_t + \alpha_5 LHC_t + e_t \qquad (1)$$

$$KS_t = \beta_0 + \beta_1 GDPGR_t + \beta_2 DE_t + \beta_3 DSE_t + \beta_4 INF_t + \beta_5 LHC_t + u_t \qquad (2)$$

where, *KS* represents stock of physical capital as percent of *GDP*, *GDPGR* denotes growth rate of *GDP* which shows economic growth performance of the economy, *EDR* is external debt to revenue ratio (or external debt as percent of total public revenue), *EDSR* is external debt service to revenue ratio (or external debt service as percent of total revenue), *INF* is consumer price index based inflation rate, *LHC* is natural logarithm of human capital proxied by gross secondary school enrolment, *EDE* is external debt to exports ratio (external debt as percent of export earnings), *EDSE* denotes external debt service to exports ratio (or external debt as percent of export earnings), *e* and *u* are random error terms.

3.2 Data and Estimation Technique

The study covers the time period from 1972 to 2016. All the required data have been sourced from the IMF's International Financial Statistic (IFS), Pakistan Economic Survey (various issues), and the World Bank's World Development Indicators (WDIs).

As data on stock of physical capital are not available in the context of Pakistan. Therefore, we have generated the absolute stock of physical capital (K) series applying the perpetual inventory method, as Caselli (2005) and Awounang and Foning (2014) did. The perpetual inventory equation is given by:

$$K_t = (1 - \rho)K_t - 1 + I_t \tag{3}$$

where *I* represents gross investment, and ρ denotes the depreciation rate. Based on the fact that data are fully available for Pakistan ranging from 1972 to 2016, we take 1972 as reference year ($Yeart_0$) to calculate the initial capital stock as follows:

$$K_{t0} = I_{t0} /(gI + \rho) \tag{5}$$

where, gI is the geometric growth rate of the aggregate investment between time t_0 and time $t_0 + t_{44}$. The choice of this formula for calculating the initial capital stock is because it is the expression of the equilibrium capital stock in the Solow growth model. Following Caselli (2005), Cavalcanti et al. (2011) and Awounang and Foning (2014) the depreciation rate of capital is taken at 6%.

The present study employs the autoregressive distributed lag (ARDL) bounds testing technique developed by Pesaran and Pesaran (1997) and Pesaran et al. (2001) to empirically estimate models (1) and (2). This technique has many advantages over other co-integration techniques. Firstly, this technique is capable enough to yield consistent parameter estimates even in the case of small data set (Mah, 2000). Secondly, this technique provides consistent results irrespective of the fact that variables are integrated of order I(0),I(1) or fractionally integrated. The ARDL representations of model (1) and (2) are as follows:

$$\Delta KS_t = \gamma_0 + \sum_{i=1}^{p} \gamma_1 \Delta KS_{t-i} + \sum_{i=0}^{p} \gamma_2 \Delta GDPGR_{t-i} + \sum_{i=0}^{p} \gamma_3 \Delta EDR_{t-i} + \sum_{i=0}^{p} \gamma_4 \Delta EDSR_{t-i} + \sum_{i=0}^{p} \gamma_5 \Delta INF_{t-i} +$$

$$\sum_{i=0}^{p} \gamma_6 \Delta LHC_{t-i} + \lambda_1 KS_{t-1} + \lambda_2 GDPGR_{t-1} + \lambda_3 EDR_{t-1} + \lambda_4 EDSR_{t-1} + \lambda_5 INF_{t-1} + \lambda_6 LHC_{t-1} + v_t \qquad (3)$$

$$\Delta KS_t = \delta_0 + \sum_{i=1}^{p} \delta_1 \Delta KS_{t-i} + \sum_{i=0}^{p} \delta_2 \Delta GDPGR_{t-i} + \sum_{i=0}^{p} \delta_3 \Delta EDE_{t-i} + \sum_{i=0}^{p} \delta_4 \Delta EDSE_{t-i} + \sum_{i=0}^{p} \delta_5 \Delta INF_{t-i} +$$

$$\sum_{i=0}^{p} \delta_6 \Delta LHC_{t-i} + \kappa_1 KS_{t-1} + \kappa_2 GDPGR_{t-1} + \kappa_3 EDE_{t-1} + \kappa_4 EDSE_{t-1} + \kappa_5 INF_{t-1} + \kappa_6 LHC_{t-1} + \varepsilon_t \qquad (4)$$

In models (3) and (4) the coefficients attached with difference operators measure short run dynamics, whereas, the terms with first lag capture long run relationship. For checking the existence of long run relationship between stock of capital and all the explanatory variables we test a separate null hypothesis of no cointegration for models (3) and (4) as:

$$\lambda_1 = \lambda_2 = \lambda_3 = \lambda_4 = \lambda_5 = \lambda_6 = 0$$

$$\kappa_1 = \kappa_2 = \kappa_3 = \kappa_4 = \kappa_5 = \kappa_6 = 0$$

For this purpose the computed F-statistic from the test is compared with critical bound values from Pesaran et al. If the null hypothesis is rejected, it will point to the existence of a cointegrating relationship between capital stock and all the regressors given in models (1) and (2). If a long run relationship is established between the variables, next step is to estimate short run dynamics and stability of equilibrium relationship between capital stock and its determinants by means of the following two error correction models:

$$\Delta KS_t = \phi_0 + \sum_{i=1}^{p} \phi_1 \Delta KS_{t-i} + \sum_{i=0}^{p} \phi_2 \Delta GDPGR_{t-i} + \sum_{i=0}^{p} \phi_3 \Delta EDR_{t-i} + \sum_{i=0}^{p} \phi_4 \Delta EDSR_{t-i} +$$

$$\sum_{i=0}^{p} \phi_5 \Delta INF_{t-i} + \sum_{i=0}^{p} \phi_6 \Delta LHC_{t-i} + \varpi ECT_{t-1} + \zeta_t \tag{5}$$

$$\Delta KS_t = \theta_0 + \sum_{i=1}^{p} \theta_1 \Delta KS_{t-i} + \sum_{i=0}^{p} \theta_2 \Delta GDPGR_{t-i} + \sum_{i=0}^{p} \theta_3 \Delta EDE_{t-i} + \sum_{i=0}^{p} \theta_4 \Delta EDSE_{t-i} +$$

$$\sum_{i=0}^{p} \theta_5 \Delta INF_{t-i} + \sum_{i=0}^{p} \theta_6 \Delta LHC_{t-i} + \pi ECT_{t-1} + \zeta_t \tag{6}$$

where, ϖ and π are coefficients of lagged error correction term (*ECT*) in equations (5) and (6) respectively. From Pesaran et al.(2001) it is evident that the coefficient of lagged ECT specifies the speed of adjustment which is linked to cointegration equation. Hence, lagged ECT characterizes the feedback of the system in stabilizing its disequilibrium. Finally, the validity of the estimated econometric model is checked by means of some important stability and diagnostic tests which are frequently employed in empirical studies.

4. Results and Discussion

The first step in the ARDL procedure is to test for unit roots to eliminate the possibility of I(2) variables. Because, in the presence of I(2) variables the computed F-statistics provided by Pesaran et al. (2001) are no more valid since they are based on the assumption that the variables are I(0) or I(1). Consequently, the implementation of unit root tests in the ARDL procedure is necessary to ensure that none of the variables are integrated of order 2 or beyond. For this reason the present study employs the Dicky-Fuller –Generalized Least Squares (DF-GLS) unit root test to check the stationarity of the time series. The DF-GLS unit root test results are reported in table 1. Results show that GDP growth rate, inflation and debt service to revenue ratio are stationary at

level, whereas, all other variables are non-stationary at level but they become stationary at first difference. Hence, it confirmed that the regressors in models (1) and (2) have mixed order of integration and none of them is integrated of order two. This outcome makes a reasonable case for using the ARDL technique for getting short run and long run parameter estimates from models (3) and (4).

Table 1. Results of DF-GLS Unit Root Test (1972-2016)

Variable	Level	First Difference	Mackinnon critical values for rejecting the unit root hypothesis (at 5%)	Decision
KS	-1.531	-5.785	-2.137	$I(1)$
GDPGR	-3.596	-	-2.137	$I(0)$
INF	-2.962	-	-2.137	$I(0)$
LHC	-1.17	-7.097	-2.137	$I(1)$
EDR	-1.160	-2.734	-2.137	$I(1)$
EDSR	-2.72	-	-2.137	$I(0)$
EDE	-1.38	-3.512	-2.137	$I(1)$
EDSE	-1.23	-6.758	-2.137	$I(1)$

The computation of the ARDL bounds testing is sensitive with lag length selection. Hence, in the second step, the orders of the lags in the ARDL models (3) and (4) are selected on each first differenced variable using the Schwarz Bayesian Criterion (SIC). Narayan and Narayan (2005) suggests that the SIC is the best for lag selection for the ARDL model with small sample[1].

We reach our decision regarding the presence of the long run relationship between the variables of the specific model with a simple comparison. i.e. the bounds approach compares the calculated F-statistic against the critical values generated by lower critical bound and upper critical

---

[1] The estimation task is executed by using the computer software EViews 9. Optimal lag length for each time series is selected the SIC with automatic lag selection option.

bound developed by Pesaran et.al. (2001). There is cointegration if the computed F-statistic is more than upper critical bound and no cointegration if the value of the F-statistic remains below the lower critical bound. However, if the sample test statistic falls between these two bounds, the result is inconclusive. All this relates to a situation when the regressors have mixed or of integration like ours. The results of the bounds testing to cointegration are displayed in tables (2). It is quite obvious that for both the models the calculated F-statistic exceeds the upper bound at 5% level of significance, indicating rejection of null hypothesis of no cointegration. Thus, stock of capital forms a long run equilibrium relationship with external debt to revenue ratio, external debt service to revenue ratio, external debt to export ratio, external debt service to export ratio, GDP growth rate, inflation and human capital in the case of Pakistan over the study period 1972 to 2016.

Table 2. Bound Test Results

Estimation	F-Test Statistic	Critical Value (5% Level of Significance)	
		Lower Bound	Upper Bound
Model 3	5.20	2.48	3.67
Model 4	5.79	2.29	3.42

4.1. Short Run and Long Run Estimates of Model (3)

The next task in ARDL bound testing technique is to investigate the extent of the long run effects of explanatory variables on the dependent variable. We now proceed with the discussion of the results of model (3) given is table 3. The regression coefficient of growth rate of GDP is significantly and positively associated with capital stock, indicating that one percent increase (decrease) in economic growth rate will result in 0.311 percent increase (decrease) in capital accumulation in Pakistan. This finding is consistent with the notion of the Accelerator Theory of Investment. The effect of external debt to revenue ratio on stock f capital is significant but negative

such that one percent increases (decrease) in the former brings a decreases (increases) of 0.08 percent in the latter. It indicates that with increase in debt to revenue ratio the uncertainty regarding the government policies and actions also increases which adversely affects the level of capital accumulation in our economy. Especially, when government's debt stock increases then such obligations are usually financed through imposing high taxes which lead to the reduction in investment and discourages the capital accumulation process. In such a situation, investors prefer to wait rather than investing in the long run projects (Agenor and Montiel, 1996). Additionally, the rapid accumulation of debt over a longer period of time may also result in massive capital outflows due to the unfavorable policies of government to finance its debt obligations (Oks and Wijnbergen, 1995). The relationship between external debt to revenue ratio and capital accumulation can also be explained through the debt overhang hypothesis which states that rising debt burden leads to decrease investment in the economy (Deshpande, 1997; Fosu, 1999; Chowdhury, 2001). Similarly, the relationship between external debt service to revenue ratio and stock of capital has also emerged as significant and negative. This outcome implies that external debt servicing puts a pressure on the available resources in the country to be diverted towards investment purposes in the economy. Increasing burden of foreign debt payments limits the financial ability of an indebted nation like Pakistan to allocate sufficient resources for building its stock of physical capital.

Table 3.Long-Run Estimates of the Model (3)

Dependent Variable: KS		Selected ARDL(1, 1, 1, 2, 1, 1)
Regressor	Coefficient	t-vaue
GDPGR	0.311**	2.699
EDR	-0.180**	-2.217
EDSR	-0.703***	-4.301
INF	-0.354***	-3.287
LHC	0.0793**	2.217
C	0.171*	1.834

Note: ***, ** and * indicate that coefficients are significant at 1% , 5% , and 10% levels
respectively.

The regression coefficient of inflation rate is negative and significant, implying that with one percent increase (decrease) in inflation rate the stock of capital decreases (increases) by 0.354 percent. A high rate of inflation raises the cost of borrowing and thus lowers the rate of capital accumulation. Similarly, higher variations in prices make it difficult for investors to estimate the costs and benefits associated with a particular project which discourages the investors to start new and long run projects (Were, 2001)). Higher rate of inflation also reduces the capital accumulation through its adverse effects on welfare of the individuals (Ahmed and Mohamed, 2005)). Finally, human capital plays a significant and positive role in capital accumulation process. However, the magnitude of the long run impact of human capital on stock of physical capital is very small that one percent increase in human capital leads to 0.079 percent increase in stock of physical capital. The result may be different if we use some other proxy of human capital. Developed human capital is considered as a valuable asset for a nation with which the nation can improve its capacity to adopt new technologies and techniques of production (Schutt, 2003; Mohsin, 2005). It also

enhances capital accumulation through creating more skills and knowledge related to the availability of investment opportunities in the economy.

Table 4 reports the short run dynamics of the model. In contrast to the long run outcomes in the short run we see that only growth rate of GDP, external debt service to revenue and human capital are significant drivers of capital accumulation in Pakistan. While rest of the regressors do not play a role in shaping the behaviour of capital accumulation. The coefficient of lagged error correction term (ECT) is negative and significant which indicates that the long run equilibrium relationship between stock of capital and all the explanatory variables given in table 3 is stable. The coefficient value of lagged ECT is -0.659, implying that reasonably high speed of adjustment towards the long run equilibrium. In other words it can be stated that in case of any deviation from the long run equilibrium, almost 66 % correction will take place in a year to restore the equilibrium position. Moreover, at the bottom of table 4, results of four diagnostic tests are given which indicate that our estimated model does not suffer from serial correction, heteroscedasticity, functional form and normality issues.

Table.4. Results of the Error Correction Model

Dependent Variable: (ΔKS)		Selected ARDL (1,1,1,2,1,1)

ΔLHC	-0.003**	-2.139
ECT(-1)	-0.659***	-5.345
Diagnostic Tests		
$\chi^2_{SC} = 0.129(0.716)$		$\chi^2_{H} = 0.851(0.356)$
$\chi^2_{FF} = 1.688(0.194)$		$\chi^2_{N} = 1.562(0.306)$

Note: ***, ** and * indicate that coefficients are significant at 1 percent, 5 percent and 10 percent levels of significance respectively. χ^2_{SC}, χ^2_{H}, χ^2_{FF} and χ^2_{N} denote LM tests for serial correlation, functional form and normality respectively. The associated p values are in parentheses.

4.2. Short Run and Long Run Estimates of Model 4

The estimated long run results of model 4 are reported in table 5. All the regressors have been found as significant factors in determining capital accumulation in the long. The impacts of growth rate of GDP, inflation rate and human capital on capital accumulation are consistent with the previous case of model 3 as displayed in table 3.The regression coefficient of external debt to export ratio is significant and negative, inferring that external debt to export ratio discourages capital accumulation process in the long run in Pakistan. This finding suggests that one percent increase in external debt to export ratio will result in nearly 0.27 percent decline in stock of capital.

The adverse effect of ratio on investment can be explained through the reduction in the import capacity of capital goods of the government which is also known as the import compression effect. According to import compression effect the increasing debt burden decreases the public investment. For the coefficient of external debt service to export ratio we also find it significant and negative such that one present increase (decrease) in debt service to export ratio decreases (increases) stock of capital by 0.143 percent. This finding presents external debt service as an impediment in the way of accelerating capital accumulation process in the long run in Pakistan. Hence, it transpires that external debt has played its adverse role in capital accumulation process during the sample period of study in the country. This outcome indicates that unfortunately we misused the borrowed fund in non-development projects. We failed to best possible productive use of the external debt which resulted in increasing external debt burden on the economy. The rising debt burden hindered the way of fostering physical capital accumulation process in Paksitan.

χ^2_{FF} = 0.341[0.728]	χ^2_{N} = 0.171(0.852)	

Note: *** and ** indicate significant at 1% and 5% levels of significance respectively.
$\chi^2_{SC}, \chi^2_{H}, \chi^2_{FF}$ and χ^2_{N} denote LM tests for serial correlation, functional form and normality respectively. The associated p values are in parentheses.

Now move come to short run analysis. From table 6 it is obvious that capital accumulation process only get affected from growth rate of GDP and external debt to export ratio where the former is positively and the latter is negatively associated with capital stock in the short run. None

of the other variables are appeared as significant factor in shaping the behaviour of stock of capital. The regression coefficient of lagged ECT is in accordance with our prior expectation i.e. it is significant and negative. From the coefficient value of lagged ECT it can be inferred that in case of an external shock to the long run equilibrium association between stock of capital and all the regressors given in table 5, the forces of the model corrects almost 79 percent disequilibrium every year, indicating a quick restoration. Finally, on the basis of four diagnostic tests, provided at the bottom of table 6, we can state that our estimated model is not plagued with any of four econometric problems. These outcomes actually increase our confidence on the overall findings of the estimated model. Finally, CUSUM and CUSUM of squares tests suggest stability of the parameter estimates of the estimated models as their plots remain within 5% level of significance (see figures 1and 2).

5. Conclusion and Policy Recommendations

This study investigates the implications of external debt for capital accumulation in Pakistan using the annual time series data covering the period from 1972 to 2016. To this end different indicators of external debt have been used and the ARDL bound testing approach to cointegration has been employed to accomplish the empirical task. The findings of the study indicate that external debt does matter for capital accumulation process in Pakistan as external debt to revenue, external debt service to revenue, external debt to export and external debt service to export ratios have been found significant and adversely related with stock of capital in the long run in Pakistan. Nonetheless, in the short run only external debt service to revenue and external debt to export ratios have emerged as significant determinants of the stock of capital. Similarly, inflation rate tends to bring a reduction while growth rate of GDP and human capital enhance the stock of capital in the long run.

Policy implications of the study are straight forward. Firstly, need is to formulate and implement some legal framework for diverting the foreign capital obtained through debt towards public sector development program. This action will stimulate business activities in the economy leading to significantly increase the stock of capital in Pakistan. Secondly, reforms should be

introduced in tax system of the country for generating sufficient resources from within the country which will help in reducing external debt to revenue ratio. A fall in external debt to revenue ratio will induce capital accumulation process. Finally, as human capital has proved a significant driver of capital accumulation, therefore, government should invest in education and skills improvement programs to enhance the general as well as specific skills of the individuals.
